

Dual, 2-MSPS, 12-Bit, 2 + 2 or 3 + 3 Channel, Simultaneous-Sampling, Analog-to-Digital Converter

Check for Samples: [ADS7863A](#)

FEATURES

- Four Fully- or Six Pseudo-Differential Inputs
- SNR: 71 dB
- THD: –81 dB
- Programmable and Buffered Internal 2.5-V Reference
- Flexible Power-Down Features
- Variable Power-Supply Ranges: 2.7 V to 5.5 V
- Low-Power Operation: 45 mW at 5 V
- Operating Temperature Range: –40°C to +125°C
- Pin-Compatible with the [ADS7861](#) and [ADS8361](#) (SSOP Package)

APPLICATIONS

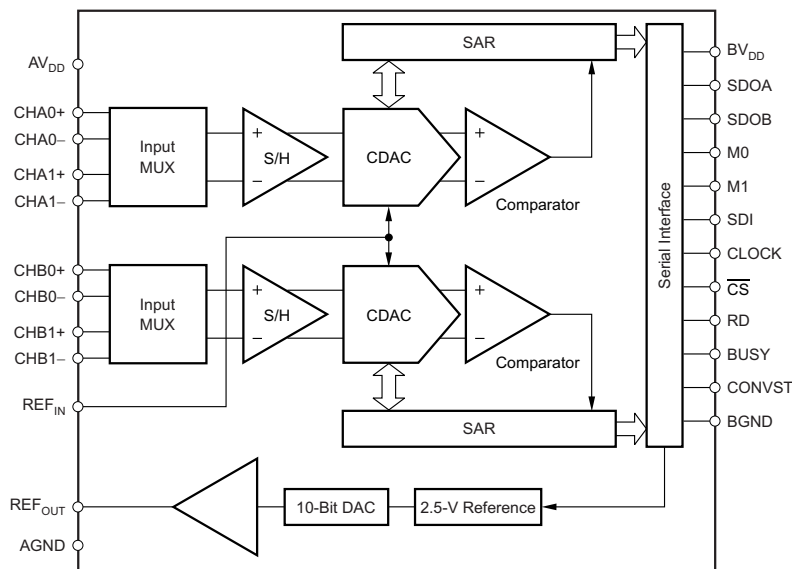

- Motor Control
- Multi-Axis Positioning Systems
- Three-Phase Power Control

DESCRIPTION

The ADS7863A is a dual, 12-bit, 2-MSPS, analog-to-digital converter (ADC) with four fully-differential or six pseudo-differential input channels grouped into two pairs for high-speed, simultaneous signal acquisition. Inputs to the sample-and-hold (S/H) amplifiers are fully differential and are maintained differential to the ADC input. This architecture provides excellent common-mode rejection of 72 dB at 100 kHz, which is a critical performance characteristic in noisy environments.

The device is pin-compatible with the [ADS7861](#), but offers additional features such as a programmable reference output, flexible supply voltage (2.7 V to 5.5 V for AV_{DD} and BV_{DD}), a pseudo-differential input multiplexer with three channels per ADC, and several power-down features.

The device is offered in an SSOP-24 and a 4-mm x 4-mm QFN-24 package. The device is specified over the extended operating temperature range of –40°C to +125°C.

Functional Block Diagram

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

All trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ORDERING INFORMATION⁽¹⁾

- (1) For the most current package and ordering information, see the Package Option Addendum at the end of this document, or visit the device product folder at www.ti.com.

ABSOLUTE MAXIMUM RATINGS⁽¹⁾

Over operating free-air temperature range, unless otherwise noted.

		VALUE	UNIT
Supply voltage	AV _{DD} to AGND	-0.3 to +6	V
	BV _{DD} to BGND	-0.3 to +6	V
	BV _{DD} to AV _{DD}	1.5 × AV _{DD}	V
Analog and reference input voltage with respect to AGND		AGND - 0.3 to AV _{DD} + 0.3	V
Digital input voltage with respect to BGND		BGND - 0.3 to BV _{DD} + 0.3	V
Ground voltage difference	AGND - BGND	0.3	V
Input current to any pin except supply pins		-10 to +10	mA
Maximum virtual junction temperature, T _J		+150	°C
Electrostatic discharge (ESD) ratings	Human body model (HBM), JEDEC standard 22, test method A114-C.01, all pins	±4000	V
	Charged device model (CDM), JEDEC standard 22, test method C101, all pins	±1500	V

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

RECOMMENDED OPERATING CONDITIONS

Over operating free-air temperature range, unless otherwise noted.

PARAMETER		MIN	NOM	MAX	UNIT
Supply voltage	AV _{DD} to AGND	2.7	5.0	5.5	V
	BV _{DD} to BGND, low voltage levels	2.7		3.6	V

EQUIVALENT INPUT CIRCUIT

Figure 1. Equivalent Input Circuit

TIMING CHARACTERISTICS

Figure 2. Detailed Timing Diagram (Mode I)

NOTE: All CONVST commands that occur more than 10 ns before the cycle 1 rising edge of the external clock (region A) initiate a conversion on the cycle 1 rising edge. All CONVST commands that occur 5 ns after the cycle 1 rising edge or 10 ns before the cycle 2 rising edge (region B) initiate a conversion on the cycle 2 rising edge. All CONVST commands that occur 5 ns after the cycle 2 rising edge (region C) initiate a conversion on the rising edge of the next clock period. The CONVST pin should never be switched from low to high in the region 10 ns prior to the CLOCK rising edge and 5 ns after the rising edge (gray areas). If CONVST is toggled in this gray area, the conversion could begin on either the same CLOCK rising edge or the following edge.

Figure 3. CONVST Timing

TIMING REQUIREMENTS⁽¹⁾

Over recommended operating free-air temperature range at -40°C to $+125^{\circ}\text{C}$, $\text{AV}_{\text{DD}} = 5\text{ V}$, and $\text{BV}_{\text{DD}} = 2.7\text{ V}$ to 5 V , unless otherwise noted.

- (1) All input signals are specified with $t_{\text{R}} = t_{\text{F}} = 1.5\text{ ns}$ (10% to 90% of BV_{DD}) and timed from a voltage level of $(V_{\text{IL}} + V_{\text{IH}}) / 2$.
- (2) Not applicable in auto-NAP power-down mode.

PIN CONFIGURATIONS

PIN DESCRIPTIONS

NAME	PIN NUMBER		DESCRIPTION
	SSOP	QFN	
AGND	12	4	Analog ground. Connect to analog ground plane.
AV _{DD}	13	5	Analog power supply, 2.7 V to 5.5 V. Decouple to AGND with a 1-μF ceramic capacitor.
BGND	1	17	Buffer I/O ground. Connect to digital ground plane.
BUSY	21	13	ADC busy indicator. BUSY goes high when the inputs are in hold mode and returns to low after the conversion finishes.
BV _{DD}	24	16	Buffer I/O supply, 2.7 V to 5.5 V. Decouple to BGND with a 1-μF ceramic capacitor.
CHA0-	9	1	Inverting analog input channel A0
CHA0+	8	24	Noninverting analog input channel A0
CHA1-	7	23	Inverting analog input channel A1
CHA1+	6	22	Noninverting analog input channel A1
CHB0-	5	21	Inverting analog input channel B0
CHB0+	4	20	Noninverting analog input channel B0
CHB1-	3	19	Inverting analog input channel B1
CHB1+	2	18	Noninverting analog input channel B1
CLOCK	20	12	External clock input
CONVST	17	9	Conversion start. The ADC switches from sample mode into hold mode on the CONVST rising edge, independent of the CLOCK status. The conversion starts with the next CLOCK rising edge.
\overline{CS}	19	11	Chip select. When low, the SDOx outputs are active; when high, the SDOx outputs 3-state.
M0	15	7	Mode pin 0. Selects between analog input channels (see Table 8).
M1	14	6	Mode pin 1. Selects between the SDOx digital outputs (see Table 8).
RD	18	10	Read data. Synchronization pulse for the SDOx outputs and SDI input. RD only triggers when \overline{CS} is low.
REF _{IN}	10	2	Reference voltage input. A 470-nF ceramic capacitor (min) is required at this terminal.
REF _{OUT}	11	3	Reference voltage output. The programmable internal voltage reference output is available on this pin.
SDI	16	8	Serial data input. This pin allows the additional device features to be used but SDI can also be used in an ADS7861-compatible manner.
SDOA	23	15	Serial data output for converter A. When M1 is high, both SDOA and SDOB are active. Data are valid on the falling CLOCK edge.
SDOB	22	14	Serial data output for converter B. Data are valid on the falling CLOCK edge.

TYPICAL CHARACTERISTICS

APPLICATIONS INFORMATION

GENERAL DESCRIPTION

The ADS7863A includes two 12-bit, analog-to-digital converters (ADCs) that operate based on the successive-approximation register (SAR) principle. The ADCs sample and convert simultaneously. Conversion time can be as low as 406.25 ns. Adding the 62.5-ns acquisition time and an additional clock cycle for setup and hold time requirements and skew results in a maximum conversion rate of 2 MSPS.

Each ADC has a fully-differential, 2:1 multiplexer front-end. In many common applications, all negative input signals remain at the same constant voltage (for example, 2.5 V). In this type of application, the multiplexer can be used in a pseudo-differential 3:1 mode, where CHx0– functions as a common-mode input and the remaining three inputs (CHx0+, CHx1–, and CHx1+) operate as separate inputs referred to the common-mode input.

The ADS7863A also includes a 2.5-V internal reference. The reference drives a 10-bit digital-to-analog converter (DAC), allowing the voltage at the REF_{OUT} pin to be adjusted via the serial interface in 2.44-mV steps. A low-noise operational amplifier with unity gain buffers the DAC output voltage and drives the REF_{OUT} pin.

The ADS7863A offers a serial interface that is compatible with the [ADS7861](#). However, instead of the A0 pin of the ADS7861 controlling channel selection, the ADS7863A offers a serial data input (SDI) pin that supports additional functions described in the [Digital](#) section (see also the [ADS7861 Compatibility](#) section).

ANALOG

This section addresses the analog input circuit, the ADCs, and the reference design of the device.

Analog Inputs

Each ADC is fed by an input multiplexer, as shown in [Figure 32](#). Each multiplexer is either used in a fully-differential 2:1 configuration (as described in [Table 1](#)) or a pseudo-differential 3:1 configuration (as shown in [Table 2](#)). The channel selection is performed using bits C1 and C0 in the SDI register (see also the [Serial Data Input](#) section).

Figure 32. Input Multiplexer Configuration

The input path for the converter is fully differential and provides a common-mode rejection of 72 dB at 100 kHz. The high CMRR also helps suppress noise in harsh industrial environments.

Table 1. Fully Differential 2:1 Multiplexer Configuration

C1	C0	ADC+	ADC–
0	0	CHx0+	CHx0–
1	1	CHx1+	CHx1–

Table 2. Pseudo-Differential 3:1 Multiplexer Configuration

C1	C0	ADC+	ADC–
0	0	CHx0+	CHx0–
0	1	CHx1–	CHx0–
1	0	CHx1+	CHx0–

Each 2-pF sample-and-hold capacitor (defined as C_S in [Figure 1](#)) is connected via switches to the multiplexer output. Opening the switches holds the sampled data during the conversion process. After finishing the conversion, both capacitors are pre-charged for the duration of one clock cycle to the voltage present at the REF_{IN} pin. After the pre-charging, the multiplexer outputs are connected to the sampling capacitors again. The voltage at the analog input pin is usually different from the reference voltage; therefore, the sample capacitors must be charged to within one-half LSB for 12-bit accuracy during the acquisition time t_{ACQ} (see the [Timing Characteristics](#)).

Acquisition time is indicated with the BUSY signal being held low. t_{ACQ} starts by closing the input switches (after finishing the previous conversion and pre-charging) and finishes with the rising edge of the CONVST signal. If the ADS7863A operates at full speed, the acquisition time is typically 62.5 ns.

The minimum –3-dB bandwidth of the driving operational amplifier can be calculated as shown in [Equation 1](#):

$$f_{-3dB} = \frac{\ln(2) \times (n + 1)}{2\pi \times t_{ACQ}}$$

where:

- $n = 12$ is the device resolution (1)

With $t_{ACQ} = 62.5$ ns, the minimum bandwidth of the driving amplifier is 23 MHz. The required bandwidth can be lower if the application allows a longer acquisition time.

A gain error occurs if a given application does not fulfill the settling requirement shown in [Equation 1](#). As a result of pre-charging the capacitors, linearity and THD are not directly affected, however.

The [OPA365](#) from Texas Instruments is recommended as a driver; in addition to offering the required bandwidth, the OPA365 provides a low offset and also offers excellent THD performance.

The phase margin of the driving operational amplifier is usually reduced by the ADC sampling capacitor. A resistor placed between the capacitor and amplifier limits this effect; therefore, an internal 200- Ω resistor (R_{SER}) is placed in series with the switch. The switch resistance (R_{SW}) is typically 50 Ω (see [Figure 1](#)).

The differential input voltage range of the ADC is $\pm V_{REF}$, the voltage at the REF_{IN} pin.

The voltage to all inputs must be kept within the 0.3-V limit below AGND and above AV_{DD} while not allowing dc current to flow through the inputs. Current is only necessary to recharge the sample-and-hold capacitors.

Analog-to-Digital Converter (ADC)

The ADS7863A includes two SAR-type, 2-MSPS, 12-bit ADCs (see the [functional block diagram](#) on the front page of this data sheet).

CONVST

The analog inputs are held with the rising edge of the CONVST (conversion start) signal. The CONVST setup time referred to the next rising edge of CLOCK (system clock) is 10 ns (minimum). The conversion automatically starts with the rising CLOCK edge. CONVST should not be issued during a conversion, that is, when BUSY is high.

RD (read data) and CONVST can be shorted to minimize necessary software and wiring. The RD signal is triggered by the ADS7863A on the falling CLOCK edge. Therefore, the combined signals must be activated with the rising CLOCK edge. The conversion then starts with the subsequent rising CLOCK edge.

CLOCK

The ADC uses an external clock in the range of 1 MHz to 32 MHz. 12 clock cycles are needed for a complete conversion; the following clock cycle is used for pre-charging the sample capacitors and a minimum of two clock cycles are required for the sampling. With a minimum of 16 clocks used for the entire process, one clock cycle is left for the required setup and hold times along with some margin for delay caused by layout. The clock input can remain low between conversions (after applying the 16th falling edge to complete a running conversion). The input can also remain low after applying the 14th falling edge during a DAC register write access if the device is not required to perform a conversion on CHBx (for example, during an initiation phase after power-up).

The CLOCK duty cycle should be 50%. However, the ADS7863A functions properly with a duty cycle between 30% and 70%.

RESET

The ADS7863A features an internal power-on-reset (POR) function. When the device is powered up, the POR sets the device in default mode when AV_{DD} reaches 1.8 V. An external software reset can be issued using the SDI register bits A[2:0] (see the [Digital](#) section).

REF_{IN}

The reference input is not buffered and is directly connected to the ADC. The converter generates spikes on the reference input voltage because of internal switching. Therefore, an external capacitor to the analog ground (AGND) should be used to stabilize the reference input voltage. This capacitor should be at least 470 nF. Ceramic capacitors (X5R type) with values up to 1 μ F are commonly available as SMD in 0402 size.

REF_{OUT}

The ADS7863A includes a low-drift, 2.5-V internal reference source. This source feeds a 10-bit string DAC that is controlled via the serial interface. As a result of this architecture, the voltage at the REF_{OUT} pin is programmable in 2.44-mV steps and can be adjusted to specific application requirements without the use of additional external components.

However, the DAC output voltage should not be programmed below 0.5 V to ensure the correct functionality of the reference output buffer. This buffer is connected between the DAC and the REF_{OUT} pin, and is capable of driving the capacitor at the REF_{IN} pin. A minimum of 470 nF is required to keep the reference stable (see the [REFIN](#) section). For applications that use an external reference source, the internal reference can be disabled using bit RP in the SDI register (see the [Digital](#) section). The settling time of the REF_{OUT} pin is 500 μ s (maximum) with the reference capacitor connected. The default value of the REF_{OUT} pin after power-up is 2.5 V.

For operation with a 2.7-V analog supply and a 2.5-V reference, the internal reference buffer requires a rail-to-rail input and output. Such buffers typically contain two input stages; when the input voltage passes the mid-range area, a transition occurs at the output because of switching between the two input stages. In this voltage range, rail-to-rail amplifiers generally show a very poor power-supply rejection.

As a result of this poor performance, the ADS7863A buffer has a fixed transition at DAC code 509 (1FDh). At this code, the DAC may show a jump of up to 10 mV in the transfer function.

DIGITAL

This section addresses the timing and control of the ADS7863A serial interface.

Serial Data Input (SDI)

The serial data input or SDI pin is coupled to RD and clocked into the ADS7863A on each falling CLOCK edge. The data word length of the SDI register is 12 bits. Table 3 shows the register structure. Data must be transferred MSB-first. Table 4 through Table 6 describe specific bits of this register. The default value of this register after power-up is 000h.

Table 3. SDI Register Contents

SDI REGISTER BIT

(1) X = don't care.

Serial Data Output (SDOx)

Converted data on the SDOx pins become valid with the third falling CLOCK edge after generating an RD pulse. The following sections explain the different modes of operation in detail.

The digital output code format of the ADS7863A is binary twos complement, as shown in [Table 9](#). Conversion results can be read out multiple times until a new conversion is issued from the CONVST input.

Timing and Control

IMPORTANT:

Consider the detailed timing diagram ([Figure 2](#)) and CONVST timing diagram ([Figure 3](#)) within the [Timing Characteristics](#) section. For maximum data throughput, the descriptions and diagrams given in this data sheet assume that the CONVST and RD pins are tied together. Note that these pins can also be controlled independently.

Device operation can be configured in four different modes by using the M0 and M1 mode pins, as shown in [Table 8](#).

Pin M0 sets either manual or automatic channel selection. In manual mode, the SDI register bits C[1:0] are used to select between channels CHx0 and CHx1; in automatic operation, the SDI register bits C[1:0] are ignored and channel selection is controlled by the device after each conversion. Pin M1 selects between serial data being transmitted simultaneously on both outputs SDOA and SDOB for each channel respectively, or using only the SDOA output for transmitting data from both channels (see [Figure 33](#) through [Figure 40](#) and the associated text for more information).

Table 8. M0, M1 Truth Table

M0	M1	CHANNEL SELECTION	SDOx USED
0	0	Manual (via SDI)	SDOA and SDOB
0	1	Manual (via SDI)	SDOA only
1	0	Automatic	SDOA and SDOB
1	1	Automatic	SDOA only

Additionally, the SDI pin is used for controlling device functionality; see the [Serial Data Input](#) section for details.

Table 9. ADS7863A Output Data Format

DESCRIPTION	DIFFERENTIAL INPUT VOLTAGE (CHxx+) – (CHxx–)	INPUT VOLTAGE AT CHxx+ (CHxx– = V _{REF} = 2.5 V)	BINARY CODE	HEXADECIMAL CODE
Positive full-scale	V _{REF}	5 V	0111 1111 1111	7FF
Mid-scale	0V	2.5 V	0000 0000 0000	000
Mid-scale – 1LSB	–V _{REF} / 4096	2.49878 V	1111 1111 1111	FFF
Negative full-scale	–V _{REF}	0 V	1000 0000 0000	800

Mode I

With the M0 and M1 pins are both set to '0', the device enters manual channel control operation and outputs data on both SDOA and SDOB, respectively. The SDI pin switches between the channels. A conversion is initiated by bringing CONVST high.

16 clock cycles are required to perform a single conversion. With the CONVST rising edge, the ADS7863A switches asynchronously to the external CLOCK from sample to hold mode.

After a delay (t_{12}), the BUSY output pin goes high and remains high for the duration of the conversion cycle. On the falling edge of the second CLOCK cycle, the ADS7863A latches in the channel for the next conversion cycle, depending on the status of the SDI register bits C[1:0]. CS must be brought low to enable both serial outputs. Data are valid on the falling edge of every 16 clock cycles per conversion. The first two bits are set to '0'. The subsequent data contain the 12-bit conversion result (the most significant bit is transferred first), followed by two '0's (see Figure 2 and Figure 33).

Figure 33. Mode I Timing Diagram (M0 = 0, M1 = 0)

Mode II

With $M0 = 0$ and $M1 = 1$, the device also operates in manual channel control mode and outputs data on the SDOA pin only when SDOB is set to 3-state. All other pins function in the same manner as they do in Mode I.

Because 32 clock cycles are required to output the results from both ADCs (instead of 16 cycles, if $M1 = 0$), the device requires $1.0 \mu\text{s}$ to perform a complete conversion or read cycle. If the CONVST signal is issued every $0.5 \mu\text{s}$ (required for the RD signal) as in Mode I, every second pulse is ignored, as shown in Figure 34.

Output data consist of a '0' followed by an ADC indicator ('0' for CHx or '1' for CHBx), 12 bits of conversion results, and another '00'.

Figure 34. Mode II Timing Diagram ($M0 = 0$, $M1 = 1$)

Mode III

With $M0 = 1$ and $M1 = 0$, the device automatically cycles between the differential inputs (ignoring the SDI register bits $C[1:0]$) while offering the conversion result of CHx on $SDOA$ and the conversion result of $CHBx$ on $SDOB$ (as shown in Figure 35).

Output data consist of a channel indicator ('0' for $CHx0$ or '1' for $CHx1$), followed by a '0', 12 bits of conversion results, and another '00'.

Figure 35. Mode III Timing Diagram ($M0 = 1, M1 = 0$)

Mode IV

In the same way as Mode II, Mode IV uses the SDOA output line exclusively to transmit data while the differential channels are switched automatically. Following the first conversion after M1 goes high, the SDOB output 3-states (as shown in Figure 36).

Output data consist of a channel indicator ('0' for CHx0 or '1' for CHx1), followed by the ADC indicator ('0' for CHAx or '1' for CHBx), 12 bits of conversion results, and end with '00'.

Figure 36. Mode IV Timing Diagram (M0 = 1, M1 = 1)

Special Mode II (Not ADS7861-Compatible)

For Mode II, a special read mode is available in the ADS7863A where both data results can be read out, triggered by a single RD pulse. To activate this mode, bit S4 in the SDI register must be set to '1' (see also the [Serial Data Input](#) section).

The CONVST and RD pins can remain tied together, but do not need to be issued every 16 CLOCK cycles. Output data are presented on both terminals, SDOA and SDOB. [Figure 37](#) illustrates the special read mode.

Figure 37. Special Mode II Timing Diagram (M0 = 0, M1 = 1, S4 = 1)

Special Mode IV (Not ADS7861-Compatible)

Analogous to Special Mode II, the device also offers a special read mode for Mode IV in which both data results of a conversion can be read, triggered by a single RD pulse. In this case as well, bit S4 in the SDI register must be set to '1' while the CONVST and RD pins can still be tied together.

As with Special Mode II, these two pins do not need to be issued every 16 CLOCK cycles. Data are available on the SDOA pin.

This special read mode (shown in Figure 38) is not available in Mode I or Mode III.

Figure 38. Special Mode IV Timing Diagram (M0 = 1, M1 = 1, S4 = 1)

Pseudo-Differential Mode I (Not ADS7861-Compatible)

In Mode I, the device input multiplexers can also operate in a pseudo-differential manner. In this case, the SDI bits (C[1:0]) are used to choose the channels accordingly.

For more details, see the [Serial Data Input](#) section. Data are available on both output terminals, SDOA and SDOB.

The input multiplexer cannot be used for pseudo-differential signals in Mode III or Mode IV.

Figure 39. Pseudo-Differential Mode I (M0 = 0, M1 = 0)

Pseudo-Differential Mode II (Not ADS7861-Compatible)

In Mode II, the device input multiplexers can also operate in a pseudo-differential configuration. In this case, output data are available on terminal SDOA only, while SDOB is held in 3-state.

Channel switching is performed by setting the C[1:0] bits in the SDI register accordingly (see also the [Serial Data Input](#) section).

The input multiplexer cannot be used for pseudo-differential signals in Mode III or Mode IV.

Figure 40. Pseudo-Differential Mode II (M0 = 0, M1 = 1)

Programming the Reference DAC (Not ADS7861-Compatible)

The internal reference DAC can be set by issuing an RD pulse while providing an SDI word with P[1:0] = 01 and A[2:0] = 001. Thereafter, a second RD pulse must be generated with an SDI word starting with the first two bits ignored, followed by the actual 10-bit DAC value (as shown in Figure 41).

To verify the DAC setting, an RD pulse must be generated while providing an SDI word containing P[1:0] = 01 and A[2:0] = 011 to initialize the DAC read access. Triggering the RD line again causes the SDOA output to send '0000' followed by the 10-bit DAC value and another '00'. During the second RD access, data present on SDI are ignored, while in Mode I and Mode III valid conversion data for channel B are present on SDOB; the conversion results of channel A are lost. The default value of the DAC register after power-up is 3FFh, corresponding to a 2.5-V reference voltage on the REF_{OUT} pin.

Figure 41. DAC Write and Read Access Timing Diagram

Power-Down Modes and Reset (Not ADS7861-Compatible)

The device has a comprehensive built-in power-down feature. There are three power-down modes: deep power-down, NAP power-down, and auto-NAP power-down. All three power-down modes are activated with the 12th falling CLOCK edge of the SDI access, during which the related bit asserts (DP = 1, N = 1, or AN = 1). All modes are deactivated by de-asserting the respective bit in the SDI register. The SDI register contents are not affected by the power-down modes. Any ongoing conversion aborts when deep or NAP power-down is initiated. [Table 10](#) lists the differences among the three power-down modes.

In *deep power-down mode*, all functional blocks except the digital interface are disabled. The bias currents of the analog block are turned off. In this mode, power dissipation reduces to 1 μ A within 2 μ s. The wake-up time from deep power-down mode is 1 μ s.

In *NAP power-down mode*, the device turns off the biasing of the comparator and the mid-voltage buffer within 200 ns. The device goes into NAP power-down mode regardless of the conversion state.

The *auto-NAP power-down mode* is very similar to NAP mode. The only differences are the methods of powering down and waking up the device. The SDI register bit AN is only used to enable or disable this feature. If the auto-NAP mode is enabled, the device turns off the biasing automatically after finishing a conversion; thus, the end of conversion actually activates the auto-NAP power-down. The device powers down within 200 ns in this mode, as well. Triggering a new conversion by applying a CONVST pulse puts the device back into normal operation and automatically starts a new conversion six CLOCK cycles later. Therefore, a complete conversion cycle takes 19 CLOCK cycles; thus, the maximum throughput rate in auto-NAP power-down mode is reduced to 1.68 MSPS.

To issue a *device reset*, an RD pulse must be generated along with an SDI word containing A[2:0] = 101. With the 12th falling edge after generating the RD pulse, the entire device (including the serial interface) is forced into reset. After approximately 500 ns, the serial interface becomes active again.

Table 10. Power-Down Modes

POWER-DOWN TYPE	ENABLED BY	ACTIVATED BY	ACTIVATION TIME	RESUMED BY	REACTIVATION TIME	DISABLED BY
Deep	DP = 1	13th clock	2 μ s	DP = 0	1 μ s	DP = 0
NAP	N = 1	13th clock	200ns	N = 0	3 clocks	N = 0
Auto-NAP	AN = 1	Each end of conversion	200ns	CONVST pulse	3 clocks	AN = 0

ADS7861 COMPATIBILITY

The ADS7863AIDBQ is pin-compatible with the ADS7861E, ADS7861EB, and ADS7861EG4. However, there are some differences between the two devices that must be considered when migrating from the ADS7861 to the ADS7863A in an existing design.

SDI versus A0

One of the differences is that pin 16 (A0), which updates the internal SDI register of the ADS7863A, is used in conjunction with M0 to select the input channel on the ADS7861.

In an existing design, if the ADS7861 is used in two-channel mode (M0 = 0) and the status of the A0 pin is unchanged within the first four clock cycles after issuing a conversion start (CONVST rising edge), the ADS7863A acts similarly to the ADS7861 and converts either channels CHx0 (if SDI is held low during the entire period) or channels CHx1 (if SDI is held high during the entire period). [Figure 34](#) describes the behavior of the ADS7863A in such a situation.

The ADS7863A can also be used to replace the ADS7861 when run in four-channel mode (M0 = 1). In this case, the A0 pin is held static (high or low) which is also required in the case of SDI to prevent accidentally updating the SDI register.

In both cases, the additional features of the ADS7863A (pseudo-differential input mode, programmable reference voltage output, and the different power-down modes) cannot be accessed but the hardware and software remain backward-compatible to the ADS7861.

REF_{IN}

The ADS7863A offers an unbuffered REF_{IN} input with a code-dependent input impedance while featuring a programmable and buffered reference output (REF_{OUT}). The ADS7861 offers a high-impedance (buffered) reference input. If an existing ADS7861-based design uses the internal reference of the device and relies on an external resistor divider to adjust the input voltage range of the ADC, migration to ADS7863A requires one of the following conditions:

- a software change to setup the internal reference DAC properly via SDI while removing the external resistors, or
- an additional external buffer between the resistor divider and the required 470-nF (minimum) capacitor on the REF_{IN} input.

In the latter case, while the capacitor stabilizes the reference voltage during the entire conversion, the buffer must recharge the capacitor by providing an average current only. The required minimum bandwidth of the buffer can be calculated using [Equation 2](#):

$$f_{-3dB} = \frac{\ln(2) \times 2}{2\pi \times 16 \times T_{CLK}} \quad (2)$$

The buffer must also be capable of driving the 470-nF load while maintaining stability.

Timing

The only timing requirement that may cause the ADS7863A to malfunction in an existing ADS7861-based design is the CONVST high time (t₁) which is specified to be 20 ns minimum while the ADS7861 works properly with a pulse as short as 15 ns. All other required minimum setup and hold times are specified to be either the same as or lower than the ADS7863A; therefore, there are no conflicts with the ADS7861 requirements.

APPLICATION INFORMATION

The absolute minimum configuration of the ADS7863A is shown in [Figure 42](#). In this case, the ADS7863A is used in dual-channel mode only, with the default settings of the device after power up.

The input signal for the amplifiers must fulfill the common-mode voltage requirements of the ADS7863A in this configuration. The actual values of the resistors and capacitors depend on the bandwidth and performance requirements of the application.

Figure 42. Minimum ADS7863A Configuration

These values can be calculated using [Equation 3](#), with $n = 12$ is the device resolution of the ADS7863A.

$$f_{\text{FILTER}} = \frac{\ln(2) \times (n + 1)}{2 \times \pi \times 2 \times R \times C}$$

where:

- $n = 12$ is the resolution of the ADS7863A (3)

TI recommends using a capacitor value of at least 20 pF.

Keep the acquisition time in mind; the resistor value can be calculated as shown in [Equation 4](#) for each of the series resistors.

$$R = \frac{t_{\text{ACQ}}}{\ln(2) \times (n + 1) \times 2 \times C}$$

where:

- $n = 12$ is the resolution of the ADS7863A (4)

LAYOUT

For optimum performance, care should be taken with the physical layout of the ADS7863A circuitry. This condition is particularly true if the CLOCK input is approaching the maximum throughput rate. In this case, TI recommends having a fixed phase relationship between CLOCK and CONVST. Best performance can be achieved when the digital interface is run in SPI mode; thus, the CLOCK signal is switched off after the 16th cycle and remains low when CONVST is issued.

Additionally, the basic SAR architecture is quite sensitive to glitches or sudden changes on the power-supply, reference, ground connections, and digital inputs that occur just before latching the output of the analog comparator. Therefore, when driving any single conversion for an n -bit SAR converter, there are n windows in which large external transient voltages can affect the conversion result. Such glitches might originate from switching power supplies, nearby digital logic, or high-power devices. The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. These errors can change if the external event also changes in time with respect to the CLOCK input.

With this possibility in mind, power to the device should be clean and well-bypassed. A 0.1- μ F ceramic bypass capacitor should be placed as close to the device as possible. In addition, a 1- μ F to 10- μ F capacitor is recommended. If needed, an even larger capacitor and a 5- Ω or 10- Ω series resistor may be used to low-pass filter a noisy supply.

If the reference voltage is external and originates from an operational amplifier, be sure that the reference voltage can drive the reference capacitor without oscillation. The connection between the output of the external reference driver and REF_{IN} should be of low resistance (10 Ω max) to minimize any code-dependent voltage drop on this path.

Grounding

The xGND pins should be connected to a clean ground reference. These connections should be kept as short as possible to minimize the inductance of these paths. TI recommends using vias connecting the pads directly to the ground plane. In designs without ground planes, the ground trace should be kept as wide as possible. Avoid connections that are too near the grounding point of a microcontroller or digital signal processor (DSP).

Depending on the circuit density of the board, placement of the analog and digital components, and the related current loops, a single solid ground plane for the entire printed circuit board (PCB) or a dedicated analog ground area may be used. In an instance of a separated analog ground area, ensure a low-impedance connection between the analog and digital ground of the ADC by placing a bridge underneath (or next to) the ADC. Otherwise, even short undershoots on the digital interface with a value lower than -300 mV lead to conduction of ESD diodes, causing current flow through the substrate and degrading the analog performance.

During PCB layout, care should also be taken to avoid any return currents crossing any sensitive analog areas or signals. No signal must exceed the limit of -300 mV with respect to the according ground plane. [Figure 43](#) illustrates the recommended layout of the ground and power-supply connections for both package options.

Supply

The ADS7863A has two separate supplies: the BV_{DD} pin for the digital interface and the AV_{DD} pin for all remaining circuits.

BV_{DD} can range from 2.7 V to 5.5 V, allowing the device to easily interface with processors and controllers. To limit the injection of noise energy from external digital circuitry, BV_{DD} should be filtered properly. Bypass capacitors of 0.1 μ F and 10 μ F should be placed between the BV_{DD} pin and ground plane.

AV_{DD} supplies the internal analog circuitry. For optimum performance, a linear regulator (for example, the [UA7805](#) family) is recommended to generate the analog supply voltage in the range of 2.7 V to 5.5 V for the ADS7863A and the necessary analog front-end circuitry.

Bypass capacitors should be connected to the ground plane such that the current is allowed to flow through the pad of the capacitor (that is, the vias should be placed on the opposite side of the connection between the capacitor and the power-supply pin of the ADC).

Digital Interface

To further optimize device performance, a resistor of 10 Ω to 100 Ω can be used on each digital pin of the ADS7863A. In this way, the slew rate of the input and output signals is reduced, limiting the noise injection from the digital interface.

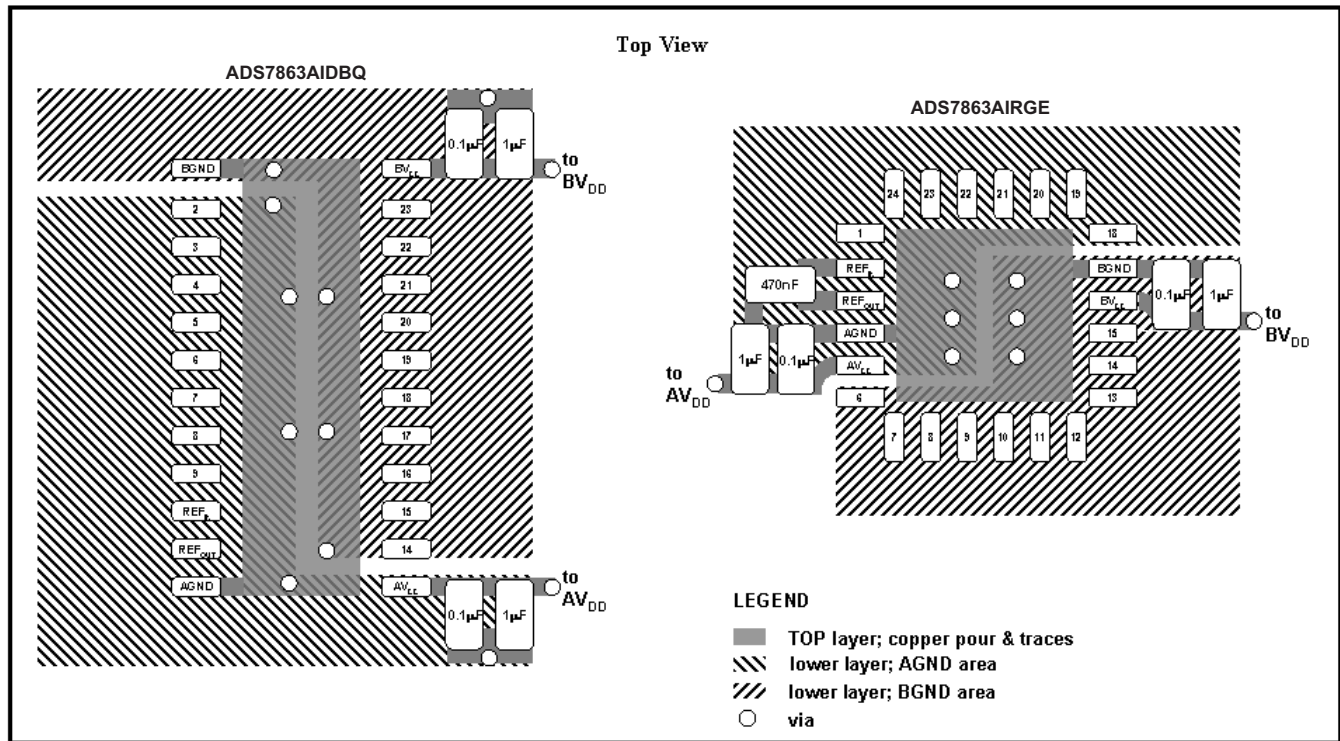

Figure 43. Optimized Layout Recommendation

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBsolete: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

4204104/G 07/11

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - B. This drawing is subject to change without notice.
 - C. Quad Flatpack, No-Leads (QFN) package configuration.
 - D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
 - E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
 - F. Falls within JEDEC MO-220.

THERMAL PAD MECHANICAL DATA

RGE (S-PVQFN-N24)

PLASTIC QUAD FLATPACK NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTES: A. All linear dimensions are in millimeters

RGE (S-PVQFN-N24)

PLASTIC QUAD FLATPACK NO-LEAD

- NOTES:
- All linear dimensions are in millimeters.
 - This drawing is subject to change without notice.
 - Publication IPC-7351 is recommended for alternate designs.
 - This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>.
 - Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
 - Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
