

LMH6554

2.8 GHz Ultra Linear Fully Differential Amplifier

General Description

The LMH6554 is a high performance fully differential amplifier designed to provide the exceptional signal fidelity and wide large-signal bandwidth necessary for driving 8 to 16 bit high speed data acquisition systems. Using National's proprietary differential current mode input stage architecture, the LMH6554 has unity gain, small-signal bandwidth of 2.8 GHz and allows operation at gains greater than unity without sacrificing response flatness, bandwidth, harmonic distortion, or output noise performance.

The device's low impedance differential output is designed to drive ADC inputs and any intermediate filter stage. The LMH6554 delivers 16-bit linearity up to 75 MHz when driving 2V peak-to-peak into loads as low as 200Ω.

The LMH6554 is fabricated in National Semiconductor's advanced complementary BiCMOS process and is available in a space saving 14 lead LLP package for higher performance.

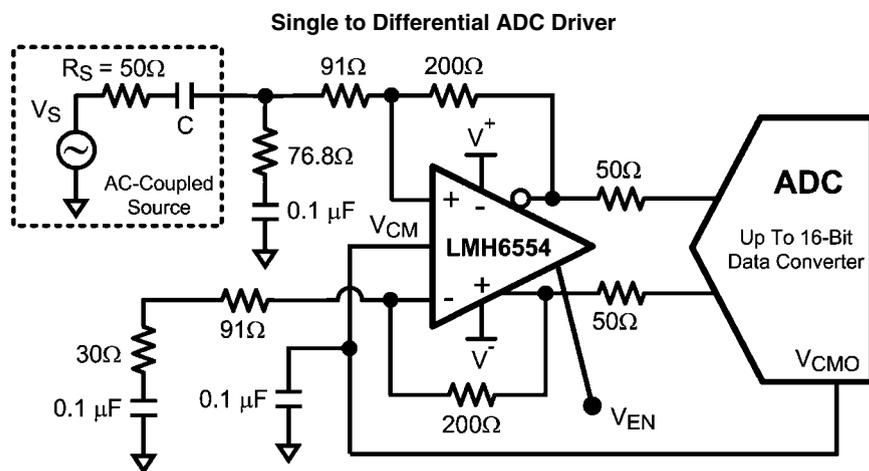

Features

■ Small signal bandwidth	2.8 GHz
■ 2 V _{PP} large signal bandwidth	1.8 GHz
■ 0.1 dB Gain flatness	830 MHz
■ OIP3 @ 150 MHz	46.5 dBm
■ HD2/HD3 @ 75 MHz	-96 / -97 dBc
■ Input noise voltage	0.9 nV/√Hz
■ Input noise current	11 pA/√Hz
■ Slew rate	6200 V/μs
■ Power	260mW
■ Typical supply current	52 mA
■ Package	14 Lead LLP

Applications

- Differential ADC driver
- Single-ended to differential converter
- High speed differential signaling
- IF/RF and baseband gain blocks
- SAW filter buffer/driver
- Oscilloscope Probes
- Automotive Safety Applications
- Video over twisted pair
- Differential line driver

Typical Application

Absolute Maximum Ratings (Note 1)

If Military/Aerospace specified devices are required, please contact the Texas Instruments Sales Office/ Distributors for availability and specifications.

ESD Tolerance (Note 5)	
Human Body Model	2000V
Machine Model	250V
Charge Device Model	750V
Supply Voltage ($V_S = V^+ - V^-$)	5.5V
Common Mode Input Voltage	From V^- to V^+
Maximum Input Current	30mA
Maximum Output Current (pins 12, 13)	(Note 4)
Soldering Information	
Infrared or Convection (30 sec)	260°C

For soldering specifications see product folder at www.ti.com and <http://www.ti.com/lit/an/snoa549c/snoa549c.pdf>

Operating Ratings (Note 1)

Operating Temperature Range	-40°C to +125°C
Storage Temperature Range	-65°C to +150°C
Total Supply Voltage Temperature Range	4.7V to 5.25V

Thermal Properties

Junction-to-Ambient Thermal Resistance (θ_{JA})	60°C/W
Maximum Operating Junction Temperature	150°C

+5V Electrical Characteristics (Note 2)

Unless otherwise specified, all limits are guaranteed for $T_A = +25^\circ\text{C}$, $A_V = +2$, $V^+ = +2.5\text{V}$, $V^- = -2.5\text{V}$, $R_L = 200\Omega$, $V_{CM} = (V^+ + V^-)/2$, $R_F = 200\Omega$, for single-ended in, differential out. Boldface Limits apply at the temperature extremes.

Symbol	Parameter	Conditions	Min (Note 8)	Typ (Note 7)	Max (Note 8)	Units

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications, see the Electrical Characteristics tables.

Note 2: Electrical Table values apply only for factory testing conditions at the temperature indicated. Factory testing conditions result in very limited self-heating of the device such that $T_J = T_A$. No guarantee of parametric performance is indicated in the electrical tables under conditions of internal self-heating where $T_J > T_A$. See Applications Section for information on temperature de-rating of this device." Min/Max ratings are based on product characterization and simulation. Individual parameters are tested as noted.

Note 3: The maximum power dissipation is a function of $T_{J(MAX)}$, θ_{JA} . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(MAX)} - T_A) / \theta_{JA}$. All numbers apply for packages soldered directly onto a PC Board.

Note 4: The maximum output current (I_{OUT}) is determined by device power dissipation limitations. See the [Power Dissipation](#) section of the Application Section for more details.

Note 5: Human Body Model, applicable std. MIL-STD-883, Method 30157. Machine Model, applicable std. JESD22-A115-A (ESD MM std. of JEDEC). Field-Induced Charge-Device Model, applicable std. JESD22-C101-C (ESD FICDM std. of JEDEC).

Note 6: Short circuit current should be limited in duration to no more than 10 seconds. See the [Power Dissipation](#) section of the Application Information for more details.

Note 7: Typical values represent the most likely parametric norm as determined at the time of characterization. Actual typical values may vary over time and will also depend on the application and configuration. The typical values are not tested and are not guaranteed on shipped production material.

Note 8: Limits are 100% production tested at 25°C. Limits over the operating temperature range are guaranteed through correlation using Statistical Quality Control (SQC) methods.

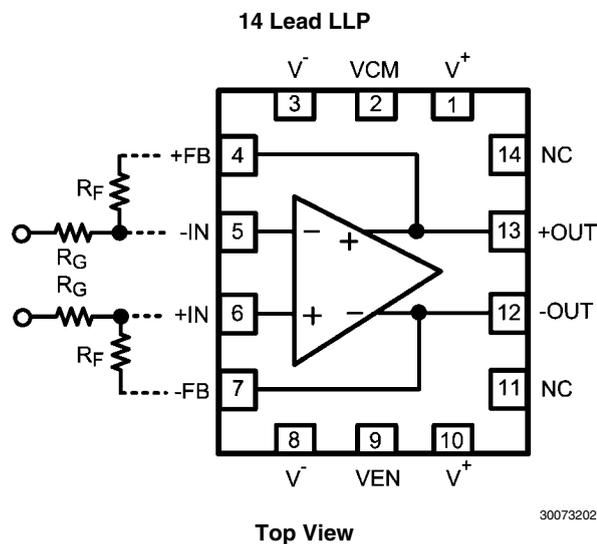

Note 9: Negative input current implies current flowing out of the device.

Note 10: I_{BI} is referred to a differential output offset voltage by the following relationship: $V_{OD(OFFSET)} = I_{BI} * 2R_F$.

Note 11: V_{EN} threshold is typically +/-0.3V centered around $(V^+ + V^-) / 2$ relative to ground.

Note 12: For test schematic, refer to [Figure 7](#).

Application Information

The LMH6554 is a fully differential, current feedback amplifier with integrated output common mode control, designed to provide low distortion amplification to wide bandwidth differential signals. The common mode feedback circuit sets the output common mode voltage independent of the input common mode, as well as forcing the V^+ and V^- outputs to be equal in magnitude and opposite in phase, even when only one of the inputs is driven as in single to differential conversion.

The proprietary current feedback architecture of the LMH6554 offers gain and bandwidth independence with exceptional gain flatness and noise performance, even at high values of gain, simply with the appropriate choice of R_{F1} and R_{F2} . Generally R_{F1} is set equal to R_{F2} , and R_{G1} equal to R_{G2} , so that the gain is set by the ratio R_F/R_G . Matching of these resistors greatly affects CMRR, DC offset error, and output balance. A maximum of 0.1% tolerance resistors are recommended for optimal performance, and the amplifier is internally compensated to operate with optimum gain flatness with R_F value of 200Ω depending on PCB layout, and load resistance.

The output common mode voltage is set by the V_{CM} pin with a fixed gain of 1 V/V. This pin should be driven by a low impedance reference and should be bypassed to ground with a $0.1\ \mu\text{F}$ ceramic capacitor. Any unwanted signal coupling into the V_{CM} pin will be passed along to the outputs, reducing the performance of the amplifier.

The LMH6554 can be configured to operate on a single 5V supply connected to V^+ with V^- grounded or configured for a split supply operation with $V^+ = +2.5\text{V}$ and $V^- = -2.5\text{V}$. Operation on a single 5V supply, depending on gain, is limited by the input common mode range; therefore, AC coupling may be required. Split supplies will allow much less restricted AC and DC coupled operation with optimum distortion performance.

Enable / Disable Operation

The LMH6554 is equipped with an enable pin (V_{EN}) to reduce power consumption when not in use. The V_{EN} pin, when not driven, floats high (on). When the V_{EN} pin is pulled low, the amplifier is disabled and the amplifier output stage goes into a high impedance state so the feedback and gain set resistors determine the output impedance of the circuit. For this reason input to output isolation will be poor in the disabled state and the part is not recommended in multiplexed applications where outputs are all tied together.

With a 5V difference between V^+ and V^- , the V_{EN} threshold is $\frac{1}{2}$ way between the supplies (e.g. 2.5V with 5V single supply) as shown in [Figure 1](#). R2 ensures active (enable) mode with V_{EN} floating, and R1 provides input current limiting. V_{EN} also has ESD diodes to either supply.

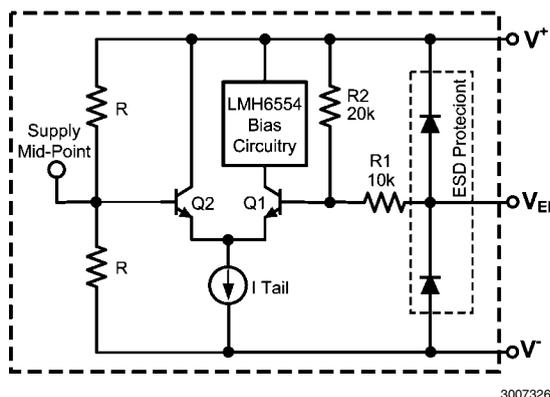

FIGURE 1. Enable Block Diagram

Fully Differential Operation

The LMH6554 will perform best in a fully differential configuration. The circuit shown in [Figure 2](#) is a typical fully differential application circuit as might be used to drive an analog to digital converter (ADC). In this circuit the closed loop gain is $A_V = V_{OUT} / V_{IN} = R_F / R_G$, where the feedback is symmetric. The series output resistors, R_O , are optional and help keep the amplifier stable when presented with a capacitive load. Refer to the [Driving Capacitive Loads](#) section for details.

Here is the expression for the input impedance, R_{IN} , as defined in [Figure 2](#):

$$R_{IN} = 2R_G$$

When driven from a differential source, the LMH6554 provides low distortion, excellent balance, and common mode rejection. This is true provided the resistors R_F , R_G and R_O are well matched and strict symmetry is observed in board layout. With an intrinsic device CMRR of greater than 70 dB, using 0.1% resistors will give a worst case CMRR of around 50 dB for most circuits.

The circuit configuration shown in [Figure 2](#) was used to measure differential S-parameters in a 100Ω environment at a gain of 1 V/V. Refer to the Differential S-Parameter vs. Frequency Plots in the Typical Performance Characteristics section for measurement results.

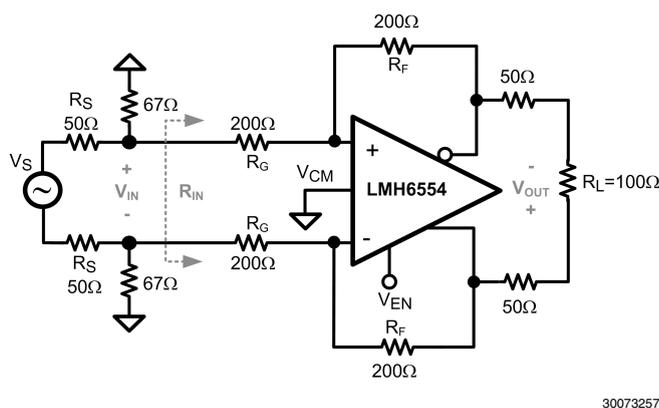

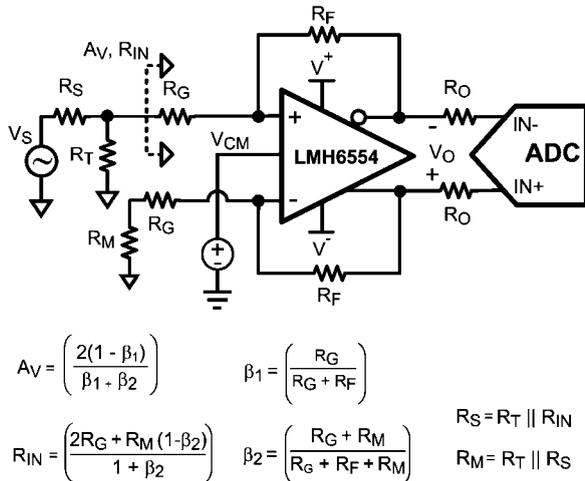

FIGURE 2. Differential S-Parameter Test Circuit

Single Ended Input To Differential Output Operation

In many applications, it is required to drive a differential input ADC from a single ended source. Traditionally, transformers have been used to provide single to differential conversion, but these are inherently bandpass by nature and cannot be used for DC coupled applications. The LMH6554 provides excellent performance as a single-ended input to differential output converter down to DC. [Figure 3](#) shows a typical application circuit where an LMH6554 is used to produce a balanced differential output signal from a single ended source.

30073258

FIGURE 3. Single Ended Input with Differential Output

When using the LMH6554 in single-to-differential mode, the complimentary output is forced to a phase inverted replica of the driven output by the common mode feedback circuit as opposed to being driven by its own complimentary input. Consequently, as the driven input changes, the common mode feedback action results in a varying common mode voltage at the amplifier's inputs, proportional to the driving signal. Due to the non-ideal common mode rejection of the amplifier's input stage, a small common mode signal appears at the outputs which is superimposed on the differential output signal. The ratio of the change in output common mode voltage to output differential voltage is commonly referred to as output balance error. The output balance error response of the LMH6554 over frequency is shown in the Typical Performance Characteristics section.

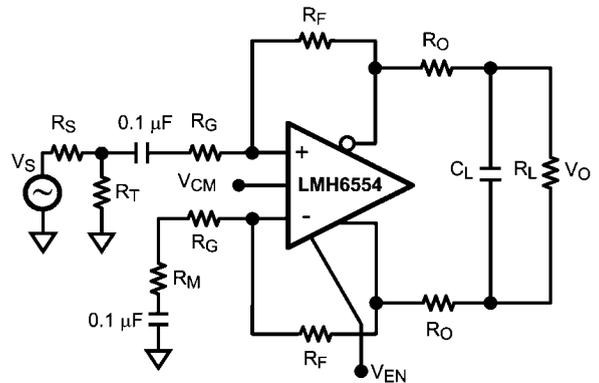

To match the input impedance of the circuit in [Figure 3](#) to a specified source resistance, R_S , requires that $R_T \parallel R_{IN} = R_S$. The equations governing R_{IN} and A_V for single-to-differential operation are also provide in [Figure 3](#). These equations, along with the source matching condition, must be solved iteratively to achieve the desired gain with the proper input termination. Component values for several common gain configuration in a 50Ω environment are given in Table 1.

Table 1. Gain Component Values for 50Ω System

Gain	R_F	R_G	R_T	R_M
0dB	200Ω	191Ω	62Ω	27.7Ω
6dB	200Ω	91Ω	76.8Ω	30.3Ω
12dB	200Ω	35.7Ω	147Ω	37.3Ω

Single Supply Operation

Single 5V supply operation is possible: however, as discussed earlier, AC input coupling is recommended due to input common mode limitations. An example of an AC coupled, single supply, single-to-differential circuit is shown in [Figure 4](#). Note that when AC coupling, both inputs need to be AC coupled irrespective of single-to-differential or differential-differential configuration. For higher supply voltages DC coupling of the inputs may be possible provided that the output common mode DC level is set high enough so that the amplifier's inputs and outputs are within their specified operation ranges.

30073260

FIGURE 4. AC Coupled for Single Supply Operation

Split Supply Operation

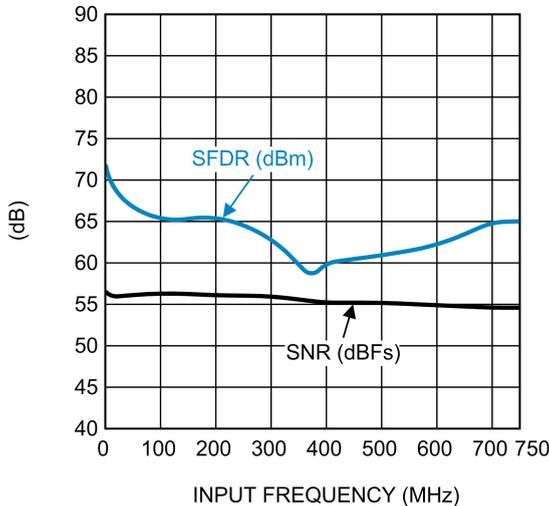

For optimum performance, split supply operation is recommended using $+2.5V$ and $-2.5V$ supplies; however, operation is possible on split supplies as low as $+2.35V$ and $-2.35V$ and as high as $+2.65V$ and $-2.65V$. Provided the total supply voltage does not exceed the $4.7V$ to $5.3V$ operating specification, non-symmetric supply operation is also possible and in some cases advantageous. For example, if a $5V$ DC coupled operation is required for low power dissipation but the amplifier input common mode range prevents this operation, it is still possible with split supplies of (V_+) and (V_-) . Where $(V_+) - (V_-) = 5V$ and V_+ and V_- are selected to center the amplifier input common mode range to suit the application.

Driving Analog To Digital Converters

Analog-to-digital converters present challenging load conditions. They typically have high impedance inputs with large and often variable capacitive components. [Figure 6](#) shows the LMH6554 driving an ultra-high-speed Gigasample ADC the ADC10D1500. The LMH6554 common mode voltage is set by the ADC10D1500. The circuit in [Figure 6](#) has a 2nd order bandpass LC filter across the differential inputs of the ADC10D1500. The ADC10D1500 is a dual channel 10-bit ADC with maximum sampling rate of 3 GSPS when operating in a single channel mode and 1.5 GSPS in dual channel mode.

[Figure 5](#) shows the SFDR and SNR performance vs. frequency for the LMH6554 and ADC10D1500 combination circuit with the ADC input signal level at -1dBFS . In order to properly match the input impedance seen at the LMH6554 amplifier inputs, R_M is chosen to match $Z_S \parallel R_T$ for proper input balance. The amplifier is configured to provide a gain of $2 V/V$ in

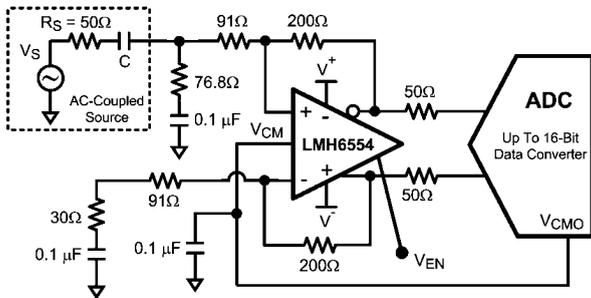

single to differential mode. An external bandpass filter is inserted in series between the input signal source and the amplifier to reduce harmonics and noise from the signal generator.

30073265

FIGURE 5. LMH6554 / ADC10D1500 SFDR and SNR Performance vs. Frequency

The amplifier and ADC should be located as close together as possible. Both devices require that the filter components be in close proximity to them. The amplifier needs to have minimal parasitic loading on its outputs and the ADC is sensitive to high frequency noise that may couple in on its inputs. Some high performance ADCs have an input stage that has a bandwidth of several times its sample rate. The sampling process results in all input signals presented to the input stage mixing down into the first Nyquist zone (DC to $F_s/2$).

30073201

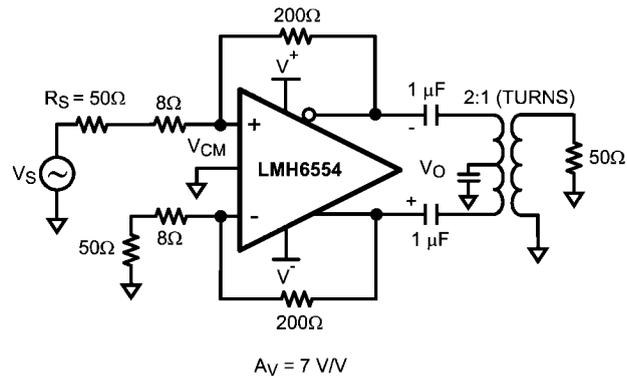

FIGURE 6. Driving a 10-bit Gigasample ADC

Output Noise Performance and Measurement

Unlike differential amplifiers based on voltage feedback architectures, noise sources internal to the LMH6554 refer to the inputs largely as current sources, hence the low input referred voltage noise and relatively higher input referred current noise. The output noise is therefore more strongly coupled to the value of the feedback resistor and not to the closed loop gain, as would be the case with a voltage feedback differential amplifier. This allows operation of the LMH6554 at much higher gain without incurring a substantial

noise performance penalty, simply by choosing a suitable feedback resistor.

Figure 7 shows a circuit configuration used to measure noise figure for the LMH6554 in a 50Ω system. A feedback resistor value of 200Ω is chosen for the LLP package to minimize output noise while simultaneously allowing both high gain (7 V/V) and proper 50Ω input termination. Refer to the *Single Ended Input To Differential Output Operation* section for the calculation of resistor and gain values.

30073261

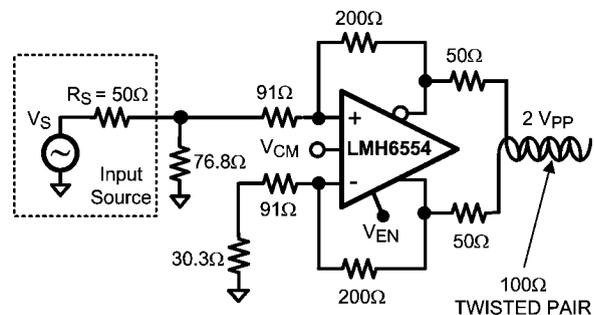

FIGURE 7. Noise Figure Circuit Configuration

Driving Capacitive Loads

As noted previously, capacitive loads should be isolated from the amplifier output with small valued resistors. This is particularly the case when the load has a resistive component that is 500Ω or higher. A typical ADC has capacitive components of around 10 pF and the resistive component could be 1000Ω or higher. If driving a transmission line, such as 50Ω coaxial or 100Ω twisted pair, using matching resistors will be sufficient to isolate any subsequent capacitance. For other applications see the Suggested R_{OUT} vs. Capacitive Load charts in the Typical Performance Characteristics section.

Balanced Cable Driver

With up to 5.68 V_{PP} differential output voltage swing the LMH6554 can be configured as a cable driver. The LMH6554 is also suitable for driving differential cables from a single ended source as shown in Figure 8.

30073262

FIGURE 8. Fully Differential Cable Driver

Power Supply Bypassing

The LMH6554 requires supply bypassing capacitors as shown in [Figure 9](#) and [Figure 10](#). The 0.01 μF and 0.1 μF capacitors should be leadless SMT ceramic capacitors and should be no more than 3 mm from the supply pins. These capacitors should be star routed with a dedicated ground return plane or trace for best harmonic distortion performance. Thin traces or small vias will reduce the effectiveness of bypass capacitors. Also shown in both figures is a capacitor from the VCM and V_{EN} pins to ground. These inputs are high impedance and can provide a coupling path into the amplifier for external noise sources, possibly resulting in loss of dynamic range, degraded CMRR, degraded balance and higher distortion.

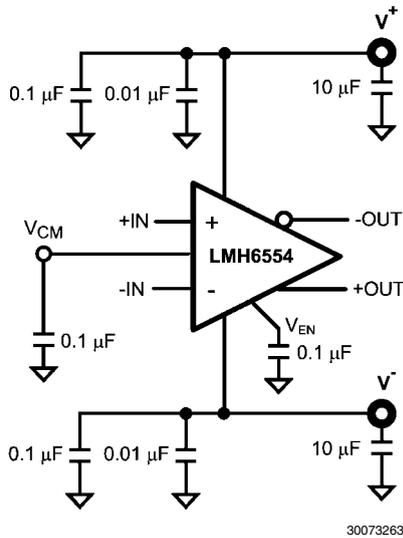

FIGURE 9. Split Supply Bypassing Capacitors

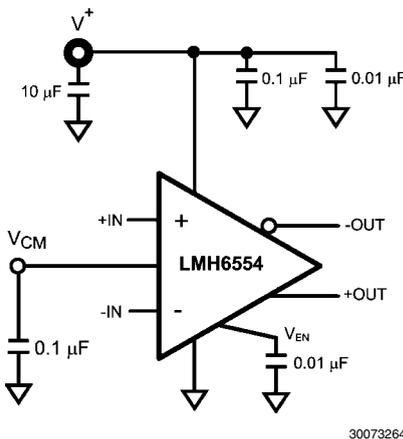

FIGURE 10. Single Supply Bypassing Capacitors

Power Dissipation

The LMH6554 is optimized for maximum speed and performance in a small form factor 14 lead LLP package. To ensure maximum output drive and highest performance, thermal shutdown is not provided. Therefore, it is of utmost importance to make sure that the T_{JMAX} is never exceeded due to the overall power dissipation.

Follow these steps to determine the maximum power dissipation for the LMH6554:

1. Calculate the quiescent (no-load) power: $P_{\text{AMP}} = I_{\text{CC}} \cdot (V_{\text{S}})$, where $V_{\text{S}} = V^{+} - V^{-}$. (Be sure to include any current through the feedback network if V_{CM} is not mid-rail).
2. Calculate the RMS power dissipated in each of the output stages: $P_{\text{D}} (\text{rms}) = \text{rms} ((V_{\text{S}} - V_{+\text{OUT}}) \cdot I_{+\text{OUT}}) + \text{rms} ((V_{\text{S}} - V_{-\text{OUT}}) \cdot I_{-\text{OUT}})$, where V_{OUT} and I_{OUT} are the voltage and the current measured at the output pins of the differential amplifier as if they were single ended amplifiers and V_{S} is the total supply voltage.
3. Calculate the total RMS power: $P_{\text{T}} = P_{\text{AMP}} + P_{\text{D}}$.

The maximum power that the LMH6554 package can dissipate at a given temperature can be derived with the following equation:

$P_{\text{MAX}} = (150^{\circ} - T_{\text{AMB}}) / \theta_{\text{JA}}$, where T_{AMB} = Ambient temperature ($^{\circ}\text{C}$) and θ_{JA} = Thermal resistance, from junction to ambient, for a given package ($^{\circ}\text{C}/\text{W}$). For the 14 lead LLP package, θ_{JA} is $60^{\circ}\text{C}/\text{W}$.

NOTE: If V_{CM} is not 0V then there will be quiescent current flowing in the feedback network. This current should be included in the thermal calculations and added into the quiescent power dissipation of the amplifier.

ESD Protection

The LMH6554 is protected against electrostatic discharge (ESD) on all pins. The LMH6554 will survive 2000V Human Body model and 250V Machine model events. Under normal operation the ESD diodes have no effect on circuit performance. There are occasions, however, when the ESD diodes will be evident. If the LMH6554 is driven by a large signal while the device is powered down the ESD diodes will conduct. The current that flows through the ESD diodes will either exit the chip through the supply pins or will flow through the device, hence it is possible to power up a chip with a large signal applied to the input pins. Using the shutdown mode is one way to conserve power and still prevent unexpected operation.

Board Layout

The LMH6554 is a high speed, high performance amplifier. In order to get maximum benefit from the differential circuit architecture board layout and component selection is very critical. The circuit board should have a low inductance ground plane and well bypassed broad supply lines. External components should be leadless surface mount types. The feedback network and output matching resistors should be composed of short traces and precision resistors (0.1%). The output matching resistors should be placed within 3 or 4 mm of the amplifier as should the supply bypass capacitors. Refer to the [Power Supply Bypassing](#) section for recommendations on bypass circuit layout. Evaluation boards are available through the product folder on National's web site.

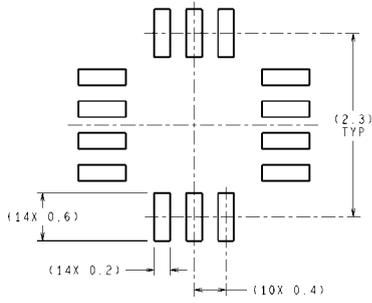

By design, the LMH6554 is relatively insensitive to parasitic capacitance at its inputs. Nonetheless, ground and power plane metal should be removed from beneath the amplifier and from beneath R_F and R_G for best performance at high frequency.

With any differential signal path, symmetry is very important. Even small amounts of asymmetry can contribute to distortion and balance errors.

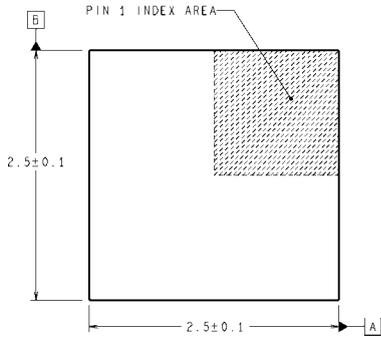

Evaluation Board

See the LMH6554 Product Folder on www.ti.com for evaluation board availability and ordering information.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
