**Rochester Electronics  
Manufactured Components**

Rochester branded components are manufactured using either die/wafers purchased from the original suppliers or Rochester wafers recreated from the original IP. All recreations are done with the approval of the OCM.

Parts are tested using original factory test programs or Rochester developed test solutions to guarantee product meets or exceeds the OCM data sheet.

**Quality Overview**

- ISO-9001
- AS9120 certification
- Qualified Manufacturers List (QML) MIL-PRF-38535
  - Class Q Military
  - Class V Space Level
- Qualified Suppliers List of Distributors (QSLD)
  - Rochester is a critical supplier to DLA and meets all industry and DLA standards.

Rochester Electronics, LLC is committed to supplying products that satisfy customer expectations for quality and are equal to those originally supplied by industry manufacturers.

*The original manufacturer's datasheet accompanying this document reflects the performance and specifications of the Rochester manufactured version of this device. Rochester Electronics guarantees the performance of its semiconductor products to the original OEM specifications. 'Typical' values are for reference purposes only. Certain minimum or maximum ratings may be based on product characterization, design, simulation, or sample testing.*

- Single-Chip Frequency-Shift-Keying (FSK) Modem
- Meet Both Bell 202 and CCITT V23 Specifications
- Transmit Modulation at 75, 150, 600, and 1200 Baud
- Receive Demodulation at 5, 75, 150, 600, and 1200 Baud
- Half-Duplex Operation Up to 1200 Baud Transmit and Receive
- Full-Duplex Operation Up to 1200 Baud Transmit and 150 Baud Receive
- On-Chip Group Equalization and Transmit/Receive Filtering
- Carrier-Detect-Level Adjustment and Carrier-Fail Output
- Single 5-V Power Supply
- Low Power Consumption
- Reliable CMOS Silicon-Gate Technology

### description

The TCM3105 is a single-chip asynchronous frequency-shift-keying (FSK) voice-band modem that uses silicon-gate CMOS technology to implement a switched-capacitor architecture. It is pin selectable (TXR1, TXR2, and TRS) for a wide range of transmit/receive baud rates and is compatible with the applicable BELL 202 or CCITT V23 standards. Operation is fully reversible, thereby allowing both forward and backward channels to be used simultaneously.

The transmitter is a programmable frequency synthesizer that provides two output frequencies (on TXA), representing the marks and spaces of the digital signal present on TXD.

The receive section is responsible for the demodulation of the analog signal appearing at the RXA input and is based on the principle of frequency-to-voltage conversion. This section contains a group delay equalizer (to correct phase distortion), automatic gain control, carrier-detect-level adjustment, and bias-distortion adjustment, thereby optimizing performance and giving the lowest possible bit error rate.

Carrier-detect information is given to the system by means of the carrier-detect circuits, which set a flag on the CDT output if the level of received in-band energy falls below a value set on the CDL input for a specified minimum duration.

The TCM3105JE and TCM3105NE are characterized for operation from  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$ . The TCM3105DWL, TCM3105JL, and TCM3105NL are characterized for operation from  $0^{\circ}\text{C}$  to  $70^{\circ}\text{C}$ .

J OR N PACKAGE  
(TOP VIEW)

DW PACKAGE  
(TOP VIEW)

NC – No internal connection

D package are available taped and reeled. Add the R suffix to device type (e.g., YCM3105DWLR).

Caution. These devices have limited built-in protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

**Terminal Functions**

TERMINAL			DESCRIPTION
NAME	NO.		
	DW	J OR N	
CDL	14	10	Carrier-detect-level adjust for external adjustment of carrier-detect threshold
CDT	3	3	Carrier-detect output. A low-level output indicates carrier failure
CLK	2	2	Output for a continuous clock signal at 16 times the highest selected (transmit or receive) bit rate
NC	4, 6, 8, 10, 15, 18, 19, 21	6	No internal connection
OSC1, OSC2	23, 24	15, 16	Oscillator connections. The crystal (typically 4.4336 MHz) is connected to OSC1 AND OSC2. If an external clock is used, OSC2 is left open and the clock is connected to OSC1.
RXA	5	4	Receive analog input to which the received line signal must be ac coupled
RXB	11	7	Receive bias adjust for external adjustment of the decision threshold of the comparator to minimize bias distortion
RXD	12	8	Receiver digital output for the demodulated received data in positive logic. The high logic level is a mark and the low logic level is a space.
RXT	9	–	Receive test access. Output of limiter is available on RXT. (DW only)
TRS	7	5	Transmit/receive standard select input, which with TXR1 and TXR2, sets the standard bit rates and mark/space frequencies
TXA	16	11	Transmit analog output for the modulation signal, which must be ac coupled
TXD	22	14	Transmit digital input for data to the transmitter in positive logic. The high logic level is a mark, and the low logic level is a space. The data can be accepted at any speed from zero to the selected speed and may be totally asynchronous.
TXR1	20	13	Bit-rate select 1 input which along with TXR2 and TRS, sets the bit rates and mark/space frequencies
TXR2	17	12	Bit rate select 2 input, which along with TXR1 and TRS, sets the bit rates and mark/space frequencies
V <sub>DD</sub>	1	1	Positive supply voltage
V <sub>SS</sub>	13	9	Most negative supply voltage (normally ground); connected to substrate

‡ Bias distortion is the departure from a 50% duty cycle when a series of alternating mark and space tones is received.

§ This is the threshold with the CDL input properly adjusted.

## PRINCIPLES OF OPERATION

The TCM3105 FSK modem is made up of four functional circuits. The circuits are the transmitter, the receiver, a carrier detector, and control and timing (see Figure 1).

**Figure 1. TCM3105 System Partitioning**

### transmitter

The transmitter comprises a phase-coherent FSK modulator, a transmit filter, and a transmit amplifier. The modulator is a programmable frequency synthesizer that drives the output frequencies by variable division of the oscillator frequency (4.4336 MHz). The division ratio is set by the states of the transmit/receive standard input (TRS), the bit-rate select inputs (TXR1 and TXR2), and the digital data input (TXD).

A switched-capacitor low-pass filter limits the harmonics and noise outside the transmit band, and the characteristics of this filter are set by the frequency-select inputs as previously described. The harmonics introduced by the transmit filter clock are removed by a continuous low-pass filter.

The transmitter output level varies with power supply voltage and so must be compensated in the 2-wire to 4-wire converter to give a constant output level to the line.

### receiver

A continuous low-pass antialiasing filter is followed by the receiver amplifier, which automatically controls the gain to give a constant output level from the receiver filter. The receiver filter limits the bandwidth of the signal presented to the demodulator reducing out-of-band interference and has very high rejection of the transmit channel frequencies. These are typically present at much higher levels than the received signal.

The group delay equalizer is a switched-capacitor network that compensates the delay introduced by the receiver filter and the network. The output from the equalizer is then limited to give an FSK modulated squarewave that is presented to the demodulator.

The demodulator is an edge-triggered multivibrator that triggers off positive- and negative-going edges. The output of the demodulator is a stream of constant-length pulses at a frequency that is double the frequency of the limited input signal. The dc component of this signal is proportional to the received frequency and is extracted by a switched-capacitor, low-pass, post-demodulator filter.

The variation of dc level with received frequency is presented to a comparator that slices at a level externally fixed by the RXB bias-adjustment pin. This voltage depends on received bit rate and internal offsets. The comparator output is then the received data at RXD.

### **carrier detect**

The carrier-detect circuits comprise an energy detector and digital delay. The energy detector compares the total signal level at the output of the receive filter to an externally set threshold level on the CDL input. The comparator has a 2.5-dB hysteresis and a delay to allow for momentary signal loss and to prevent oscillation. The output detector is available on CDT where a high level indicates that a carrier is present. The data output is clamped to a mark condition when the carrier-detect output switches off at the end of transmission.

### **control and timing**

An on-chip oscillator runs from an external 4.4336-MHz crystal connected between OSC1 and OSC2 or an external signal driving OSC1. A clock signal equal to 16 times the highest selected bit rate (transmit or receive) is available on the CLK output.

The single-supply rail means that all analog functions are referenced to an internally generated reference. All analog inputs and outputs must be ac coupled.

### **transmit and receive modes**

The various modes of operation of the TCM3105 are given in Table 1. The data convention is that a logic high is a mark and a logic low is a space.
